We calculate the \( B \to D^{(*)} \) form factors in the heavy-quark and large-recoil limits in the perturbative QCD framework based on the \( k_T \) factorization theorem, assuming the hierarchy \( M_B \gg M_{D^{(*)}} \gg \tilde{\Lambda} \), with the B meson mass \( M_B \), the \( D^{(*)} \) meson mass \( M_{D^{(*)}} \), and the heavy meson and heavy quark mass difference \( \tilde{\Lambda} \). The qualitative behavior of the light-cone \( D^{(*)} \) meson wave function and the associated Sudakov resummation are derived. The leading-power contributions to the \( B \to D^{(*)} \) form factors, characterized by the scale \( \tilde{\Lambda} \sqrt{M_B/M_{D^{(*)}}} \), respect the heavy-quark symmetry. The next-to-leading-power corrections in \( 1/M_B \) and \( 1/M_{D^{(*)}} \), characterized by a scale larger than \( \sqrt{\tilde{\Lambda} M_B} \), are estimated to be less than 20%. The \( D^{(*)} \) meson wave function is determined from the fit to the observed \( B \to D^{(*)} l \nu \) decay spectrum, which can be employed to make predictions for nonleptonic decays, such as \( B \to D^{(*)} \pi \rho \).

**I. INTRODUCTION**

Recently, we have made theoretical progress in the perturbative QCD (PQCD) approach to heavy-to-light decays, such as the proof of the \( k_T \) factorization theorem [1], the construction of power counting rules for various topologies of decay amplitudes [2], the derivation of \( k_T \) and threshold resummations [3–5], and the application to heavy baryon decays [6] and to three-body nonleptonic decays [7]. The important dynamics in the decays \( B \to K \pi \) and \( B \to \pi \pi \pi \) has been explored, including penguin enhancement and large \( CP \) asymmetries [2,8–10]. It is worthwhile to investigate to what extent this formalism can be generalized to charmful decays, such as the semileptonic decay \( B \to D^{(*)} l \nu \) and the nonleptonic decay \( B \to D^{(*)} \pi \rho \). The \( k_T \) factorization theorem for the \( B \to D^{(*)} \) form factors in the large-recoil region of the \( D^{(*)} \) meson can be proven following the procedure in Ref. [1], which is expressed as the convolution of hard amplitudes with \( B \) and \( D^{(*)} \) meson wave functions. A hard amplitude, being infrared finite, is calculable in perturbation theory. The \( B \) and \( D^{(*)} \) meson wave functions, collecting the infrared divergences in the decays, are not calculable but universal.

The \( B \to D^{(*)} \) transitions are more complicated than the \( B \to \pi \) ones, because they involve three scales: the \( B \) meson mass \( M_B \), the \( D^{(*)} \) meson mass \( M_{D^{(*)}} \), and the heavy meson and heavy quark mass difference \( \tilde{\Lambda} = M_B - m_B - M_{D^{(*)}} - m_c \), where \( m_B(m_c) \) is the \( b(c) \) quark mass and \( \tilde{\Lambda} \) is of order of the QCD scale \( \Lambda_{QCD} \). There are several interesting topics in the large-recoil region of the \( B \to D^{(*)} \) transitions. (1) How do we construct reasonable power counting rules for these decays with the three scales? (2) What is the qualitative behavior of the wave function for an energetic \( D^{(*)} \) meson? Is it dominated by soft dynamics, the same as a \( B \) meson wave function, or by collinear dynamics, the same as a pion wave function? (3) How different are the end-point singularities in the \( B \to D^{(*)} \) form factors from those in the \( B \to \pi \) ones? (4) What is the effect of Sudakov \( (k_T \text{ and threshold}) \) resummation in the \( B \to D^{(*)} \) form factors? (5) How are the relations for the \( B \to D^{(*)} \) form factors in the heavy-quark limit modified by the finite \( B \) and \( D^{(*)} \) meson masses? (6) What is the hard scale for the \( B \to D^{(*)} \) transitions? Is it large enough to make sense out of perturbative evaluation of hard amplitudes? These questions will be answered in this work.

We attempt to develop PQCD formalism for the \( B \to D^{(*)} l \nu \) decays in the heavy-quark and large-recoil limits based on \( k_T \) factorization theorem [11,12]. We argue that the following hierarchy must be postulated:

\[
M_B \gg M_{D^{(*)}} \gg \tilde{\Lambda}. \tag{1}
\]

The relation \( M_B \gg M_{D^{(*)}} \) justifies the perturbative analysis of the \( B \to D^{(*)} \) form factors at large recoil and the definition of light-cone \( D^{(*)} \) meson wave functions. The relation \( M_{D^{(*)}} \gg \tilde{\Lambda} \) justifies the power expansion in the parameter \( \tilde{\Lambda}/M_{D^{(*)}} \). We shall calculate the \( B \to D^{(*)} \) form factors as double expansions in \( M_{D^{(*)}}/M_B \) and in \( \tilde{\Lambda}/M_{D^{(*)}} \). The small ratio \( \tilde{\Lambda}/M_B = (M_{D^{(*)}}/M_B) (/\tilde{\Lambda}/M_{D^{(*)}}) \) is regarded as being of higher power. Whether the hierarchy is reasonable can be examined by the convergence of high-order corrections in the strong coupling constant \( \alpha_s \) and of higher-power corrections in \( 1/M_B \) and in \( 1/M_{D^{(*)}} \). Note that Eq. (1) differs from the small-velocity limit considered in Ref. [13], where the ratio \( M_{D^{(*)}}/M_B \) is treated as being of \( O(1) \).

Under the hierarchy, the wave function for an energetic \( D^{(*)} \) meson absorbs collinear dynamics, but with the \( c \) quark line being eikonalized. That is, its definition is a mixture of...
those for a $B$ meson dominated by soft dynamics and for a pion dominated by collinear dynamics. We examine the behavior of the heavy meson wave functions in the heavy-quark and large-recoil limits. For $\tilde{A}/M_B$, $\tilde{A}/M_{D^{(*)}} \leq 1$, only a single $B$ meson wave function $\phi_B(x)$ and a single $D^{(*)}$ meson wave function $\phi_{D^{(*)}}(x)$ are involved in the $B \to D^{(*)}$ form factors, $x$ being the momentum fraction associated with the light spectator quark. Equations of motion for the relevant nonlocal matrix elements imply that $\phi_B(x)$ and $\phi_{D^{(*)}}(x)$ exhibit maxima at $x \sim \tilde{A}/M_B$ and at $x \sim \tilde{A}/M_{D^{(*)}}$, respectively. Since PQCD is reliable in the large-recoil region, it is powerful for the study of two-body nonleptonic behavior of the heavy meson wave functions in the heavy-pion dominated by collinear dynamics. We examine the behavior derived from this consideration. It has been proved that predictions for a physical quantity can be made by using a tool more appropriate than collinear factorization at the $B \to D\pi$ decay. Preliminary results for the $B \to D\pi$ modes will be presented in Sec. IV.

Similar to the heavy-to-light transitions, the $B \to D^{(*)}$ form factors also suffer singularities from the end-point region with a momentum fraction $x = 0$ in collinear factorization theorem. When the end-point region is important, the parton transverse momenta $k_T$ are not negligible, and $k_T$ factorization is a tool more appropriate than collinear factorization. It has been proved that predictions for a physical quantity derived from $k_T$ factorization are gauge invariant [1]. Because of the inclusion of parton transverse degrees of freedom, the large double logarithmic corrections $a_{\infty} \ln k_T$ appear and should be summed to all orders. It turns out that the resultant Sudakov factor for an energetic $D^{(*)}$ meson is similar to that for a $B$ meson. Including the Sudakov effects from $k_T$ resummation and from threshold resummation for hard amplitudes [5,14], the end-point singularities do not exist, and soft contributions can be suppressed effectively.

We shall identify the leading-power and next-to-leading-power (down by $1/M_B$ or by $1/M_{D^{(*)}}$) contributions to the $B \to D^{(*)}$ form factors, which are equivalent to the expansion in heavy quark effective theory [15,16]. It will be shown that the leading-power factorization formulas satisfy the heavy-quark relations defined in terms of the Isgur-Wise (IW) function [15]. These contributions are characterized by the scale $\Lambda(M_B/M_{D^{(*)}})$, indicating that the applicability of PQCD to the $B \to D^{(*)}$ form factors may be marginal. The next-to-leading-power corrections to the heavy-quark relations, characterized by a scale larger than $\sqrt{\tilde{A}M_B}$, can be evaluated more reliably. These corrections amount only up to 20% of the leading contribution, indicating that the power expansion in $1/M_B$ and in $1/M_{D^{(*)}}$ works well. It should be stressed that the above percentage is only indicative, since we have not yet been able to explore the complete next-to-leading-power sources with the current poor knowledge of nonperturbative inputs.

In Sec. II we define kinematics and explain $k_T$ factorization theorem for the $B \to D^{(*)}\ell\nu$ decay. The power counting rules are constructed. In Sec. III we discuss the behavior of the $B$ and $D^{(*)}$ meson wave functions, and perform $k_T$ resummation associated with an energetic $D^{(*)}$ meson. The leading-power and next-to-leading-power contributions to the $B \to D^{(*)}$ form factors are calculated in Sec. IV. Section V is the conclusion.

II. KINEMATICS AND FACTORIZATION

We discuss kinematics of the $B \to D^{(*)}\ell\nu$ decay in the large-recoil region. The $B$ meson momentum $P_1$, and the $D^{(*)}$ meson momentum $P_2$ are chosen, in the light-cone coordinates, as

$$P_1 = \frac{M_B}{\sqrt{2}} (1,1,0), \quad P_2 = \frac{r^{(*)}M_B}{\sqrt{2}} (\eta^+, \eta^-, 0),$$

(2)

with the ratio $r^{(*)} = M_{D^{(*)}}/M_B$. The factors $\eta^\pm = \eta = \pm \sqrt{2-\eta^2}$ is defined in terms of the velocity transfer $\eta = v_1 - v_2$ with $v_1 = P_1/M_B$ and $v_2 = P_2/M_{D^{(*)}}$. The longitudinal polarization vector $\epsilon_\perp$ and the transverse polarization vectors $\epsilon_T$ of the $D^*$ meson are then given by

$$\epsilon_\perp = \frac{1}{\sqrt{2}} (\eta^+, -\eta^-, 0), \quad \epsilon_T = (0,0,1).$$

(3)

The partons involved in hadron wave functions are close to the mass shell [17]. Assume that the heavy meson, the heavy quark, and the light spectator quark carry the momenta $P_H, P_Q = P_H - k$, and $k$, respectively. The on-shell conditions lead to

$$k^2 = O(\tilde{A}^2),$$

(4)

$$P_Q^2 - m_Q^2 = M_H^2 - m_Q^2 - 2P_H \cdot k = O(\tilde{A}^2),$$

(5)

$M_H(m_Q)$ being the heavy meson (quark) mass. For the $B$ meson, we have $2P_1 \cdot k = 2M_B k_1^0 - M_B^2 - m_b^2 = 2M_B\tilde{A}$ from Eq. (5), namely, $k_1^0 \sim \tilde{A}$. The order of magnitude of the light spectator momentum is then, from Eq. (4),

$$k_1^0 \sim (\tilde{A}, \tilde{A}, \tilde{A}).$$

(6)

For the $D^{(*)}$ meson, we have $2P_2 \cdot k_2 = 2P_2^+ k_2^- + 2P_2^- k_2^+ \sim 2M_{D^{(*)}}\tilde{A}$, which implies

$$k_2^\mu \sim \left( \frac{M_B}{M_{D^{(*)}}} \right)^{\frac{1}{2}} \tilde{A},$$

(7)

for $\eta^\pm \sim 1/\rho^{(*)}$ and $\eta^- \sim r^{(*)}$. With the above parton momenta, the exchanged gluon in the lowest-order diagrams is off-shell by

$$(k_1 - k_2)^2 \sim - \frac{M_B}{M_{D^{(*)}}} \tilde{A}^2,$$

(8)

which is identified as the characteristic scale of the hard amplitudes. To have a meaningful PQCD formalism, the large-recoil limit in Eq. (1), $M_B \gg M_{D^{(*)}}$, is necessary.

We have proved $k_T$ factorization theorem for the semileptonic decay $B \to \pi\ell\nu$ [1]. Soft divergences from the region of
a loop momentum $l$, where all its components are of $O(\bar{\Lambda})$, are absorbed into a light-cone $B$ meson wave function. Collinear divergences from the region with $l$ parallel to the pion momentum in the plus direction, whose components scale as $l^\mu \sim (M_B, \bar{\Lambda}^2/M_B, \bar{\Lambda})$, are absorbed into a pion wave function. The above meson wave functions, defined as nonlocal hadronic matrix elements, are gauge-invariant and universal.

$k_T$ factorization theorem for the semileptonic decay $B \rightarrow D^{(*)}\nu$ is similar. In the limit $M_B \gg M_{D^{(*)}}$, we have $k_T^+ \gg k_T^- \gg k_T^0$ from Eq. (7), indicating that the $D^{(*)}$ meson wave function is dominated by collinear dynamics. The leading infrared divergences in this decay are then classified as being soft, if a loop momentum $l$ vanishes like $l^\mu \sim (\Lambda, \bar{\Lambda}, \bar{\Lambda})$, and as being collinear, if $l$ scales as $k_2$ in Eq. (7). The former (latter) are collected into a light-cone $B(D^{(*)})$ meson wave function. The collinear gluons defined by Eq. (9) do not lead to infrared divergences.

Though the $D^{(*)}$ meson wave function is collinear, similar to the pion wave function, the heavy-quark expansion applies to the $b$ quark in a $B$ meson. This is the reason we claim that the energetic $D^{(*)}$ meson dynamics is a mixture of those of the $B$ meson at rest and of the energetic pion. Because $p_B \cdot l \sim M_{D^{(*)}} \bar{\Lambda}$ is much larger than $l^2 \sim \bar{\Lambda}^2$ according to Eq. (1), we have the eikonal approximation

$$P_2 - k^2 + l^2 - m_c^2 \gamma^\mu \gamma^\nu c(P_2 - k^2) \approx \frac{u_2^\alpha}{u_2 \cdot l} c(P_2 - k^2),$$

with $c(P_2 - k^2)$ is the $c$ quark spinor, and the factor $u_2^\alpha/(u_2 \cdot l)$ the Feynman rule for a rescaled $c$ quark field. The physics involved in the above approximation is that the kinematics of the spectator quark and of the $c$ quark is dramatically different in the limit $M_{D^{(*)}} \rightarrow \infty$. Hence, a gluon moving parallel to $k_2$ can not resolve the details of the $c$ quark, from which its dynamics decouples.

According to $k_T$ factorization theorem [1], the light spectator momenta $k_1$ in the $B$ meson and $k_2$ in the $D^{(*)}$ meson are parametrized as

$$k_1 = \left(0, x_1 \frac{M_B}{\sqrt{2}} k_1T \right), \quad k_2 = \left(x_2 \eta^+ + r^{(*)} \frac{M_B}{\sqrt{2}} 0, k_2T \right),$$

where the momentum fractions $x_1$ and $x_2$ have the orders of magnitude

$$x_1 \sim \bar{\Lambda}/M_B, \quad x_2 \sim \bar{\Lambda}/M_{D^{(*)}}.$$

The smallest component $k_1^+$ is dropped. The neglect of $k_1^-$ is due to its absence in the hard amplitudes shown below.

The lowest-order diagrams for the $B \rightarrow D^{(*)}$ form factors are displayed in Fig. 1. The factorization formula is written as

$$\langle D^{(*)}(P_2)|\bar{b} \Gamma \mu c|B(P_1)\rangle$$

$$= g^2 C_F N_c \int du_1 du_2 d^2k_1 d^2k_2 \frac{dz^+ d^2z_- dy^- d^2y_+}{(2\pi)^3 (2\pi)^3}$$

$$\times e^{-ik_2 \cdot \vec{z}} \langle D^{(*)}(P_2)|\vec{d}_y(0)c_\mu(0)\rangle e^{ik_1 \cdot \vec{z}}$$

$$\times \langle 0|\bar{b}_a(0)d_\delta(\vec{z})|B(P_1)\rangle H^{\mu;\delta}_{\mu},$$

with the hard amplitude

$$H^{\mu;\delta}_{\mu} = \left[\gamma_\mu\right]^{\gamma_\delta} \frac{1}{(k_2 - k_1)^2} \left[\gamma^\mu \frac{k_2 - P_1 + m_b}{(P_1 - k_2)^2 - m_b^2} \Gamma_\mu \right]^{\alpha\beta}$$

$$+ \left[\gamma_\mu\right]^{\gamma_\delta} \frac{1}{(k_2 - k_1)^2} \left[\Gamma_\mu \frac{k_1 - P_2 + m_c}{(P_2 - k_1)^2 - m_c^2} \gamma^\mu \right]^{\alpha\beta}$$

for $\Gamma_\mu = \gamma_\mu$ or $\gamma_\mu \gamma_5$. It is obvious that the large component $k_2^+$ picks up only the component $k_1^+$ in the denominators of the internal particle propagators. The first and second terms in $H^{\mu;\delta}_{\mu}$ behave as $M_{D^{(*)}}^2/(\bar{\Lambda}^2 M_B^2)$ and $M_{D^{(*)}}^2/(\bar{\Lambda}^2 M_B^2)$, respectively. Therefore, for a leading-power formalism, we keep $O(1)$ coefficients of the first term, and $O(r^{(*)})$ coefficients [$O(1)$ coefficients are absent] of the second term.

### III. HEAVY MESON WAVE FUNCTIONS

In this section we discuss the qualitative behavior of the $B$, $D$, and $D^*$ meson wave functions in the heavy-quark and large-recoil limits, and derive $k_T$ resummation associated with the $D^{(*)}$ meson.

#### A. B meson wave functions

According to Refs. [1,18,19], the two leading-twist $B$ meson wave functions defined via the nonlocal matrix element

$$\int \frac{d^4 w}{(2\pi)^4} e^{ik \cdot w}(0|\bar{b}_a(0)d_\delta(\vec{w})|B^{0}(P))$$

$$= -\frac{i}{\sqrt{2N_c}} \left[ (P + M_B) \gamma_5 \times \left( \frac{\phi_{a+}}{\sqrt{2}}(k) + \frac{h}{\sqrt{2}} \phi_{a-}(k) \right) \right]_{\alpha\delta},$$

(15)
with the dimensionless vectors \( n = (1, 0, 0) \) and \( n = (0,1,0) \) on the light cone, and the wave functions

\[
\phi_B = \phi_B^+, \quad \bar{\phi}_B = (\phi_B - \phi_B^+)/\sqrt{2}.
\]

(17)

We have shown that the contribution from \( \bar{\phi}_B \) starts from the next-to-leading-power \( \bar{\Lambda}/M_B \). This contribution, which may be numerically relevant [20], should be included together with other next-to-leading-power contributions in order to form a complete analysis. On this point, our opinion is contrary to that in Ref. [21].

The investigation based on equations of motion [22] shows that the distribution amplitude \( \phi_B^+(x) = \int \mathfrak{d}^2k \phi_B^+(x,kT) \) vanishes at the end points of the momentum fraction \( x = k^+/P^+ \rightarrow 0, 1 \). Hence, we adopt the model in the impact parameter space \( \mathbf{b} \) [8]

\[
\phi_B(x,b) = N_B x^2(1-x)^2 \exp \left[ -\frac{1}{2} \left( \frac{x M_B}{\omega_B} \right)^2 - \frac{\omega_B^2 b^2}{2} \right],
\]

(18)

where the shape parameter \( \omega_B \) has been determined as \( \omega_B = 0.4 \) GeV. The normalization constant \( N_B \) is related to the decay constant \( f_B \) through

\[
\int dx \phi_B(x,b=0) = \frac{f_B}{2 \sqrt{2N_c}}.
\]

(19)

It is easy to find that \( \phi_B \) in Eq. (18) has a maximum at \( x \sim \bar{\Lambda}/M_B \) as claimed in Sec. II.

**B. D meson wave functions**

Consider the nonlinear matrix elements associated with the \( D \) meson,

\[
\langle 0 | \bar{c}(y) \gamma_5 \gamma_\mu d(w)| \bar{D}^-(P) \rangle \\
= -i f_D P_\mu \int_0^1 dx e^{-i(p^- k^-) \cdot y - ik \cdot w} \phi_B^* (x) \\
- \frac{i}{2} f_D M_D^2 \frac{z_\mu}{P \cdot z} \int_0^1 dx e^{-i(p^- k^-) \cdot y - ik \cdot w} g_D (x),
\]

(20)

\[
\langle 0 | \bar{c}(y) \gamma_5 d(w)| \bar{D}^-(P) \rangle \\
= -i f_D m_0 \int_0^1 dx e^{-i(p^- k^-) \cdot y - ik \cdot w} \phi_B^* (x),
\]

(21)

\[
\langle 0 | \bar{c}(y) \gamma_5 \sigma_{\mu \nu} d(w)| \bar{D}^-(P) \rangle \\
= -\frac{i}{6} f_D m_0 \left( 1 - \frac{M_D^2}{m_0^2} \right) (P \mu \nu \nu - P \nu \nu \mu) \\
\times \int_0^1 dx e^{-i(p^- k^-) \cdot y - ik \cdot w} \phi_B^* (x),
\]

(22)

(0|\bar{c}(y)\gamma_5 \sigma_{\mu \nu} d(w)|D^-(P))

\[
= -\frac{i}{6} f_D m_0 \left( 1 - \frac{M_D^2}{m_0^2} \right) (P \mu \nu \nu - P \nu \nu \mu) \\
\times \int_0^1 dx e^{-i(p^- k^-) \cdot y - ik \cdot w} \phi_B^* (x),
\]

(22)

with \( z = y - w \) and the \( D \) meson decay constant \( f_D \). The light spectator \( d \) quark carries the momentum \( k \) with the momentum fraction \( x = k^+/P^+ \) and the \( \bar{c} \) quark carries the momentum \( P - k \). In the heavy-quark limit we have

\[
m_0 = \frac{M_D^2}{m_c + m_d} = M_D + O(\bar{\Lambda}),
\]

(23)

implying that the contribution from the distribution amplitude \( \phi_D^* \) is suppressed by \( O(\bar{\Lambda}/M_D) \) compared to those from \( \phi_B^* \) and \( \phi_B^* \). The distribution amplitude \( g_D \), appearing at \( O(\bar{\Lambda}^2) \), is negligible.

Rewrite the psudotensor matrix element as

\[
\langle 0 | \bar{c}(y) \gamma_5 \sigma_{\mu \nu} d(w)| \bar{D}^-(P) \rangle \\
= i \langle 0 | \bar{c}(y) \gamma_5 \gamma_\mu d(w)| \bar{D}^-(P) \rangle \\
- ig_{\mu \nu} \langle 0 | \bar{c}(y) \gamma_5 d(w)| \bar{D}^-(P) \rangle,
\]

(24)

and differentiate both sides with respect to \( w \) and \( y \). The differentiation on the left-hand side gives a result suppressed by \( O(\bar{\Lambda}/M_D) \). The relations

\[
\int dxx \phi_D^* (x) e^{-i(p^- k^-) \cdot y - ik \cdot w} = O(\bar{\Lambda}/M_D),
\]

(25)

\[
\int dx \left[ \phi_D^* (x) - \phi_B^* (x) \right] e^{-i(p^- k^-) \cdot y - ik \cdot w} = O(\bar{\Lambda}/M_D),
\]

(26)

arise from the differentiation with respect to \( w \), for \( \mu = - \) and to \( y_\mu \) for \( \nu = + \), respectively. Equation (25) states that the distribution amplitude \( \phi_D^* \) possesses a maximum at \( x \sim \bar{\Lambda}/M_D \). Equation (26) states that the moments of \( \phi_D^* \) and \( \phi_B^* \) differ by \( O(\bar{\Lambda}/M_D) \) (they have the same normalizations).

Neglecting the \( O(\bar{\Lambda}/M_D) \) difference according to Eq. (1), only a single \( D \) meson wave function is involved in the evaluation of the \( B \rightarrow D \) form factors

\[
\int \frac{d^4w}{(2\pi)^4} e^{ik \cdot w} \langle 0 | \bar{c}(0) d(y) | \bar{D}^-(P) \rangle \\
= -\frac{i}{\sqrt{2N_c}} [(P + M_D) \gamma_5] \gamma_\rho \phi_B^* (x),
\]

(27)

where the distribution amplitude
\[ \phi_D = \frac{f_D}{2\sqrt{2N_c}} \phi_D^0 = \frac{f_D}{2\sqrt{2N_c}} \phi_D^0 \] (28)

satisfies the normalization
\[ \int_0^1 dx \phi_D(x) = \frac{f_D}{2\sqrt{2N_c}}. \] (29)

For the purpose of numerical estimate, we adopt the simple model
\[ \phi_D(x) = \frac{3}{\sqrt{2N_c}} f_D x (1 - x) \left[ 1 + C_D (1 - 2x) \right]. \] (30)

The free shape parameter \( C_D \) is expected to take a value, such that \( \phi_D \) has a maximum at \( x \sim \bar{A}/M_D \sim 0.3 \). We do not consider the intrinsic \( b \) dependence of the \( D \) meson wave function, which can be introduced along with more free parameters. Note that Eq. (30) differs from the one of the Gaussian form proposed in Ref. [23].

**C. \( D^* \) meson wave functions**

The information of the \( D^* \) meson distribution amplitudes is extracted from equations of motions for the nonlocal matrix elements
\[
\langle 0 | \bar{c}(y) \gamma_\mu d(w) | D^{*-}(P, \epsilon) \rangle = f_{D^*} M_{D^*} \left[ P_\mu \frac{\epsilon \cdot z}{P \cdot z} \int_0^1 dx e^{-ip \cdot (P-k) \cdot y - ik \cdot w} \phi_\parallel(x) \right.
\]
\[ + \epsilon T_\mu \int_0^1 dx \frac{e^{-ip \cdot (P-k) \cdot y - ik \cdot w} g_\perp^{(v)}(x)}{2} - \frac{1}{2} \epsilon \cdot z \frac{z}{(P \cdot z)^2} M_{D^*}^2 \left[ \int_0^1 dx e^{-ip \cdot (P-k) \cdot y - ik \cdot w} g_3(x) \right], \] (31)

\[
\langle 0 | \bar{c}(y) \sigma_{\mu\nu} d(w) | D^{*-}(P, \epsilon) \rangle = \left( P_\mu \epsilon_\nu - P_\nu \epsilon_\mu \right) \int_0^1 dx e^{-ip \cdot (P-k) \cdot y - ik \cdot w} \phi_\perp(x) \]
\[ + \left( P_\mu \epsilon_\nu - P_\nu \epsilon_\mu \right) \frac{e \cdot z}{(P \cdot z)^2} M_{D^*}^2 \left[ \int_0^1 dx \right.
\]
\[ \times e^{-ip \cdot (P-k) \cdot y - ik \cdot w} h_1^{(*)} + \frac{1}{2} \epsilon T_\mu \epsilon_\nu - \epsilon T_\nu \epsilon_\mu \frac{M_{D^*}^2}{P \cdot z} h_3(x) \left. \right], \] (32)

\[
\langle 0 | \bar{c}(y) \gamma_\mu \gamma_5 d(w) | D^{*-}(P, \epsilon) \rangle = -i f_{D^*} M_{D^*} \epsilon_\mu \epsilon_T P \cdot \zeta \left[ \int_0^1 dx \right.
\]
\[ \times e^{-ip \cdot (P-k) \cdot y - ik \cdot w} h_1^{(*)} + \frac{1}{2} \epsilon T_\mu \epsilon_\nu - \epsilon T_\nu \epsilon_\mu \frac{M_{D^*}^2}{P \cdot z} \]
\[ \left. \right], \] (33)

\[
\langle 0 | \bar{c}(y) \gamma_5 \gamma_\mu d(w) | D^{*-}(P, \epsilon) \rangle = -f_{D^*} M_{D^*} \epsilon_\mu \epsilon_T P \cdot \zeta \left[ \int_0^1 dx \right.
\]
\[ \times e^{-ip \cdot (P-k) \cdot y - ik \cdot w} h_2^{(*)} \left. \right], \] (34)

where the \( D^* \) meson decay constant \( f_{D^*} = f_{D^*}^T \) is associated with the longitudinal (transverse) polarization.

In the heavy-quark limit we have
\[
f_{D^*}^T = f_{D^*} M_{D^*} \left( -f_{D^*}^T - f_{D^*} M_{D^*} \right) - O(\bar{A}/M_D). \] (35)

Hence, the contributions from the various distribution amplitudes are characterized by the powers
\[
\phi_0(x), \phi_\perp(x): O(1),
\]
\[
g_\parallel^{(*)}(x), h_\parallel^{(*)}(x): O(r^*),
\]
\[
g_\perp^{(*)}(x), h_\perp^{(*)}(x): O(\bar{A}/M_D),
\] (36)

To the current accuracy, we shall consider the distribution amplitudes \( \phi_0(x) \) and \( h_\parallel^{(*)}(x) \) for the longitudinal polarization, and \( \phi_\perp(x) \) and \( g_\perp^{(*)}(x) \) for the transverse polarization of the \( D^* \) meson.

We rewrite the tensor matrix element as
\[
\langle 0 | \bar{c}(y) \sigma_{\mu\nu} d(w) | D^{*-}(P) \rangle = i \langle 0 | \bar{c}(y) \gamma_\mu \gamma_5 d(w) | D^{*-}(P) \rangle
\]
\[ - i g_{\mu\nu} \langle 0 | \bar{c}(y) d(w) | D^{*-}(P) \rangle, \] (37)

and differentiate both sides with respect to \( w \) and \( y \). The relations
\[
\int dx \langle \phi_\parallel(x) + h_3(x) \rangle e^{-ip \cdot (P-k) \cdot y - ik \cdot w} = O(\bar{A}/M_D), \] (38)

\[
\int dx \left[ \phi_\parallel(x) + h_3(x) \right] e^{-ip \cdot (P-k) \cdot y - ik \cdot w} = O(\bar{A}/M_D), \] (39)
come from the derivatives with respect to \(w\) for \(\mu = -\), to \(w\) for \(\mu = \pm\), to \(y_\mu\) for \(\nu = -\), to \(y_\mu\) for \(\nu = +\), and to \(y_\mu\) for \(\nu = \pm\), respectively. Equations (38) and (39) indicate that the \(D^*\) meson distribution amplitudes have maxima at \(x \sim \bar{\Lambda}/M_{D^*}\). Equations (40) and (41) state that \(\phi_1^L, h_{1}^{(v)}\), and \(g_3\) are identical up to corrections of \(O(\bar{\Lambda}/M_{D^*})\). Similarly, \(\phi_1, h_3,\) and \(g_3^{(v)}\) are also identical up to corrections of \(O(\bar{\Lambda}/M_{D^*})\) from Eq. (42).

Neglecting the \(O(\bar{\Lambda}/M_{D^*})\) difference, we consider the structure for a \(D^*\) meson

\[
\int \frac{d^4w}{(2\pi)^4} e^{ik\cdot w} (0) \bar{c}_\mu(0) d_j(w) |D^*^{-}(P)\rangle
\]

\[= -i \left[ \left( (P + M_{D^*}) \vec{\epsilon}_T \phi_{D^*}^T(x) \right)_{\gamma\beta} + (P + M_{D^*}) \vec{\epsilon}_T \phi_{D^*}^T(x) \right]_{\gamma\beta} \]

with the definitions

\[\phi_{D^*}^L = \frac{f_{D^*}}{2\sqrt{2N_c}} \phi_1 = \frac{f_{D^*}}{2\sqrt{2N_c}} h_{1}^{(v)},\]

\[\phi_{D^*}^T = \frac{f_{D^*}}{2\sqrt{2N_c}} \phi_1 = \frac{f_{D^*}}{2\sqrt{2N_c}} g_3^{(v)}.\]

The \(D^*\) meson distribution amplitudes satisfy the normalizations

\[\int_0^1 dx \phi_{D^*}^L(x) = \int_0^1 dx \phi_{D^*}^T(x) = \frac{f_{D^*}}{2\sqrt{2N_c}},\]

where we have assumed \(f_{D^*} = f_{D^*}^L\). Note that equations of motion do not relate \(\phi_{D^*}^L\) and \(\phi_{D^*}^T\). In this work we shall simply adopt the same model

\[\phi_{D^*}^L(x) = \phi_{D^*}^T(x) = \frac{3}{\sqrt{2N_c}} f_{D^*} x (1 - x) [1 + C_{D^*}(1 - 2x)].\]

Similarly, the free shape parameter \(C_{D^*}\) is expected to take a value, such that \(\phi_{D^*}\) has a maximum at \(x \sim \bar{\Lambda}/M_{D^*} \sim 0.3\).
with the quark anomalous dimension $\gamma = -\alpha_s/\pi$. For the explicit expression of the Sudakov exponent $s$, refer to Ref. [8]. It is found that Eq. (49) has the same functional form as the Sudakov factor for the B meson.

The double logarithms $\alpha_s \ln^2 x$ produced by the radiative corrections to the hard amplitudes are the same as in the $B \to \pi \rho$ decays at leading power in $1/M_B$ and in $1/M_{D(*)}$. Threshold resummation of these logarithms leads to

$$S_\ell(x) = \frac{2^{1+2c} \Gamma(3/2+c)}{\sqrt{\pi} \Gamma(1+c)} [x(1-x)]^c,$$

with the constant $c = 0.3 \sim 0.4$. The factor $S_\ell(x_2) [S_\ell(x_1)]$, associated with the first (second) term of $H_{D*B}$ in Eq. (14), suppresses the end-point region with $x_2 \to 0$ ($x_1 \to 0$). In the numerical study below we shall adopt $c = 0.35$.

**IV. $B \to D, D^*$ FORM FACTORS**

The $B \to D(*)$ transitions are defined by the matrix elements

$$\langle D(P_2)|\bar{b}(0)\gamma_\mu c(0)|B(P_1)\rangle = \sqrt{M_B M_D} \{ \xi_+(\eta)(v_1 + v_2)_\mu + \xi_-(\eta)(v_1 - v_2)_\mu \},$$

$$\langle D^*(P_2,\epsilon^*)|\bar{b}(0)\gamma_\mu \gamma_5 c(0)|B(P_1)\rangle = \sqrt{M_B M_{D^*}} \{ \xi_A(\eta)(\eta + 1) \epsilon^*_\mu - \xi_A(\eta) \epsilon^* \cdot v_1 v_2_\mu - \xi_A(\eta) \epsilon^* \cdot v_1 v_2_\mu \},$$

$$\langle D^*(P_2,\epsilon^*)|\bar{b}(0)\gamma_\mu c(0)|B(P_1)\rangle = i \sqrt{M_B M_{D^*}} \xi_V(\eta) \epsilon^{*\alpha\beta} \epsilon^*_\mu v_2 \cdot v_1 \beta \cdot v_2 \cdot v_1 \beta.$$

The form factors $\xi_+, \xi_-, \xi_A, \xi_A^1, \xi_A^2, \xi_V$ satisfy the relations in the heavy-quark limit

$$\xi_+ = \xi_- = \xi_A = \xi_A^1 = \xi_A^2 = \xi, \quad \xi_- = \xi_A = 0,$$

where $\xi$ is the Isgur-Wise (IW) function [15].

We write the form factors as the sum of the leading-power and next-to-leading-power contributions

$$\xi_i = \xi_i^{(0)} + \xi_i^{(1)}$$

for $i = +, -, A_1, A_2, A_3, V$. The leading-power factorization formulas are given by

$$\xi_+^{(0)} = 16\pi C_F \sqrt{\eta} M_B^2 \int dx_1 dx_2 \int b_1 b_2 b_2 b_2 \phi_B(x_1, b_1) \times \phi_D(x_2) [E(t^{(1)})h(x_1, x_2, b_1, b_2) + rE(t^{(2)})h(x_2, x_1, b_2, b_1)],$$

$$\xi_-^{(0)} = 0,$$

$$\xi_A^{(0)} = 0.$$
\[ \xi_1 = -4 \pi C_F \sqrt{\mu} M_B^2 \int dx_1 dx_2 \int b_1 db_1 b_2 db_2 \phi_B(x_1, b_1) \]
\[ \times \phi_D(x_2) \left( \eta^+ + 1 \right) \frac{\eta^+ - 2}{\sqrt{\eta^+ - 1}} [r x_2 E(t^{(1)}) \]
\[ \times h(x_1, x_2, b_1, b_2) - x_1 E(t^{(2)}) h(x_2, x_1, b_2, b_1)], \]

(62)

\[ \xi_{A1}^{(1)} = 8 \pi C_F \sqrt{\mu} M_B^2 \int dx_1 dx_2 \int b_1 db_1 b_2 db_2 \phi_B(x_1, b_1) \]
\[ \times \phi_D(x_2) \left[ \frac{\eta^+ - 2}{\eta^+ + 1} r \right] x_2 E(t^{(1)}) h(x_1, x_2, b_1, b_2) \]
\[ - \frac{x_1}{\eta^+ + 1} E(t^{(2)}) h(x_2, x_1, b_2, b_1) \],

(63)

\[ \xi_{A2}^{(1)} = -16 \pi C_F \sqrt{\mu} M_B^2 \int dx_1 dx_2 \int b_1 db_1 b_2 db_2 \phi_B(x_1, b_1) \phi_D(x_2) \]
\[ \times \eta^+ x_1 \frac{r}{\sqrt{\eta^+ - 1}} E(t^{(2)}) \]
\[ \times h(x_2, x_1, b_2, b_1), \]

(64)

\[ \xi_{A3, v}^{(1)} = -8 \pi C_F \sqrt{\mu} M_B^2 \int dx_1 dx_2 \int b_1 db_1 b_2 db_2 \phi_B(x_1, b_1) \phi_D(x_2, b_2) \]
\[ \times \left[ \frac{\eta^+ - 2}{\sqrt{\eta^+ - 1}} r \right] x_2 E(t^{(1)}) h(x_1, x_2, b_1, b_2) \]
\[ - \frac{x_1}{\sqrt{\eta^+ - 1}} E(t^{(2)}) h(x_2, x_1, b_2, b_1) \],

(65)

whose hard amplitudes are consistent with those obtained in Refs. [24–26]. The additional powers in \( x_2 \) and in \( x_1 \) provide stronger suppression in the end-point region with \( x_1, x_2 \rightarrow 0 \). Hence, the characteristic hard scales of the corresponding terms increase to \( \sqrt{\lambda M_B} \) and to \( M_B \sqrt{\lambda/M_{D^{(*)}}} \), respectively.

Consider the expansion of the currents to \( O(1/m_B) \) and \( O(1/m_c) \) [27]

\[ \bar{b} \Gamma_i c = \bar{b}_i \Gamma_i c + \frac{1}{2 m_c} \bar{b}_i \Gamma_i D_2 c - \frac{1}{2 m_b} \bar{b}_i \Gamma_i D_1 c + \cdots, \]

(66)

where the ellipses stand for the terms which are further suppressed by \( \alpha_s \). Compared to the right-hand side of Eq. (66), \( \xi_i^{(0)} \) and the terms proportional to \( x_2 \) (\( x_i \) in \( \xi_i^{(1)} \)) are identified as the first term and the second (third) term. We do not distinguish \( M_B \) and \( m_b \), and \( M_{D^{(*)}}, m_c, \) and \( m_0 \), and employ only one single wave function for the \( B \) and \( D^{(*)} \) mesons. The differences of the above quantities are also the sources of \( 1/m \) corrections. However, their estimation requires more information of nonperturbative inputs, and cannot be performed in this work. Equations (61)–(65) will be employed to obtain an indication of the order of magnitude of next-to-leading-power corrections to the \( B \rightarrow D^{(*)} \) form factors.

It is observed from Fig. 3(a) that most of the contribution to the form factor \( \xi_i^{(0)} \) comes from the range of \( \alpha_s/\pi < 0.3 \), implying that the applicability of PQCD to the \( B \rightarrow D^{(*)} \) form factors is acceptable, and not worse than that to the \( B \rightarrow \pi \) ones [4]. This is attributed to the fact that the hard scales \( \sqrt{\lambda M_B/M_{D^{(*)}}} \) and \( \sqrt{\lambda M_B} \) in the two cases do not differ very much. The applicability improves for the next-to-leading-power contributions as shown in Fig. 3(b); most of them arise from \( \alpha_s/\pi < 0.2 \). We emphasize that the above percentage analysis is only indicative, and that the convergence of higher-order corrections needs to be justified by explicit calculation. We estimate from Fig. 4 that next-to-leading-power contributions are less than 20% of the leading one. In fact, they are small except \( \xi_{A2}^{(1)} \), implying that the power expansion in \( \sqrt{\lambda M_B} \) and in \( \sqrt{\lambda M_{D^{(*)}}} \) is reliable. Our results are smaller than those obtained from QCD sum rules at large recoil [28].

The next step is to determine the \( D^{(*)} \) meson distribution amplitudes, i.e., the free parameters \( C_{D^{(*)}} \), by fitting the leading-power PQCD predictions to the measured decay spectra at large recoil [29–31]. The \( 1W \) function extracted from the \( B \rightarrow D^{(*)}\ell \nu \) decay is parameterized as
respectively. Choosing the decay constants \( f_B \) and \( f_D \) with the factors those derived from lattice calculations, the B normalization of the heavy-quark symmetry defines unambiguously the D decays. Therefore, one of the purposes of this work is to determine the unknown \( D^{(*)} \) meson wave function. The B meson and pion wave functions have been fixed already in the literature. With these meson wave functions being available, we are able to predict the branching ratios of two-body nonleptonic charmful decays, such as \( B \to D^{(*)}\pi(\rho) \). Our predictions for the \( B \to D \pi \) branching ratios [35]

\[
B(B^- \to D^0\pi^-) \sim 5.5 \times 10^{-3}, \\
B(B^0 \to D^+\pi^-) \sim 2.8 \times 10^{-3}, \\
B(B^0 \to D^0\pi^0) \sim 2.6 \times 10^{-4}
\]

are in agreement with experimental data [36–38]. The above results correspond to the phenomenological coefficients \( a_1 \) and \( a_2 \) [39] with the ratio \( |a_2/a_1| \sim 0.5 \) and the phase \( -57^\circ \) of \( a_2 \) relative to \( a_1 \). The point is, from the viewpoint of PQCD, that the phase is of short distance and generated from hard amplitudes. This is contrary to the conclusion drawn from naive factorization [39–42]: the phase comes from long-distance final-state interaction.

If the \( D^{(*)} \) meson decay constant is known from, for example, lattice QCD calculation, it is then possible to extract the matrix element \( |V_{cb}| \) from the measured semileptonic decay spectra at large recoil using the PQCD formalism. The experimental data for the \( B \to D l\nu \) mode [29] are listed in Table I. The region with the large velocity transfer \( \eta > 1.35 \) is regarded as the one, where PQCD analyses are reliable. We compute the following \( \chi \)
TABLE I. Experimental data of $|V_{cb}|\xi(\eta)$ for the $B\to D l \nu$ decay.

The factorization formulas for the $B\to D^{(*)}$ transitions in the heavy-quark and large-recoil limits based on $k_T$ factorization theorem. The reasonable power counting rules for these decays with the three scales $M_B$, $M_{D^{(*)}}$, and $\Lambda$ have been constructed following the hierarchy in Eq. (1). Under this hierarchy, only a single $B$ meson wave function and a single $D^{(*)}$ meson wave function are involved, which possess maxima at the spectator momentum fractions $x \sim \Lambda/M_B$ and $x \sim \Lambda/M_{D^{(*)}}$, respectively. Dynamics of an energetic $D^{(*)}$ meson is the mixture of those of a $B$ meson at rest and of an energetic light meson: it absorbs collinear divergences but the heavy-quark expansion applies to the $c$ quark. The Sudakov factor from $k_T$ resummation for an energetic $D^{(*)}$ meson is similar to that associated with a $B$ meson. The end-point singularities, being logarithmic in the collinear factorization theorem, do not exist in the $k_T$ factorization theorem. Including also the Sudakov effect from threshold resummation for hard amplitudes, the PQCD approach to the $B\to D^{(*)}$ transitions becomes more reliable.

The factorization formulas for the $B\to D^{(*)}$ form factors have been expressed as the sum of leading-power and next-to-leading-power contributions, which is equivalent to the heavy-quark expansion in both $1/m_c$ and $1/m_c$. The leading-power formulas, respecting the heavy-quark symmetry, are identified as the IW function. This contribution, characterized by the scale $\Lambda\sqrt{M_B/M_{D^{(*)}}}$, is calculable marginally in PQCD. The next-to-leading-power corrections, characterized by a scale larger than $\Lambda\sqrt{M_B}$, can be estimated more reliably, and are found to be less than 20% of the leading contribution. That is, the heavy-quark expansion makes sense. Note that the next-to-leading-power corrections considered here, which can be analyzed under the current knowledge of nonperturbative inputs, are not complete. The conclusion drawn in this paper provides a solid theoretical base for the PQCD analysis of the $\Lambda_b$ baryon charmful decays [43].

We have determined the $D^{(*)}$ meson wave function from the $B\to D^{(*)}\nu$ decay spectrum, which has a maximum at the spectator momentum fraction $x \sim 0.36$ as expected. This wave function is useful for making predictions for the two-body nonleptonic decays in the PQCD formalism. The results of the $B\to D\pi$ branching ratios have been presented in Eq. (69), which are consistent with the experimental data. The details of this subject will be published elsewhere.

V. CONCLUSION

In this paper we have developed the PQCD formalism for the $B\to D^{(*)}$ transitions in the heavy-quark and large-recoil limits based on $k_T$ factorization theorem. The reasonable power counting rules for these decays with the three scales $M_B$, $M_{D^{(*)}}$, and $\Lambda$ have been constructed following the hierarchy in Eq. (1). Under this hierarchy, only a single $B$ meson wave function and a single $D^{(*)}$ meson wave function are involved, which possess maxima at the spectator momentum fractions $x \sim \Lambda/M_B$ and $x \sim \Lambda/M_{D^{(*)}}$, respectively. Dynamics of an energetic $D^{(*)}$ meson is the mixture of those of a $B$ meson at rest and of an energetic light meson: it absorbs collinear divergences but the heavy-quark expansion applies to the $c$ quark. The Sudakov factor from $k_T$ resummation for an energetic $D^{(*)}$ meson is similar to that associated with a $B$ meson. The end-point singularities, being logarithmic in the collinear factorization theorem, do not exist in the $k_T$ factorization theorem. Including also the Sudakov effect from threshold resummation for hard amplitudes, the PQCD approach to the $B\to D^{(*)}$ transitions becomes more reliable.

The factorization formulas for the $B\to D^{(*)}$ form factors have been expressed as the sum of leading-power and next-to-leading-power contributions, which is equivalent to the heavy-quark expansion in both $1/m_c$ and $1/m_c$. The leading-power formulas, respecting the heavy-quark symmetry, are identified as the IW function. This contribution, characterized by the scale $\Lambda\sqrt{M_B/M_{D^{(*)}}}$, is calculable marginally in PQCD. The next-to-leading-power corrections, characterized by a scale larger than $\Lambda\sqrt{M_B}$, can be estimated more reliably, and are found to be less than 20% of the leading contribution. That is, the heavy-quark expansion makes sense. Note that the next-to-leading-power corrections considered here, which can be analyzed under the current knowledge of nonperturbative inputs, are not complete. The conclusion drawn in this paper provides a solid theoretical base for the PQCD analysis of the $\Lambda_b$ baryon charmful decays [43].

We have determined the $D^{(*)}$ meson wave function from the $B\to D^{(*)}\nu$ decay spectrum, which has a maximum at the spectator momentum fraction $x \sim 0.36$ as expected. This wave function is useful for making predictions for the two-body nonleptonic decays in the PQCD formalism. The results of the $B\to D\pi$ branching ratios have been presented in Eq. (69), which are consistent with the experimental data. The details of this subject will be published elsewhere.
